

## Classes and Objects

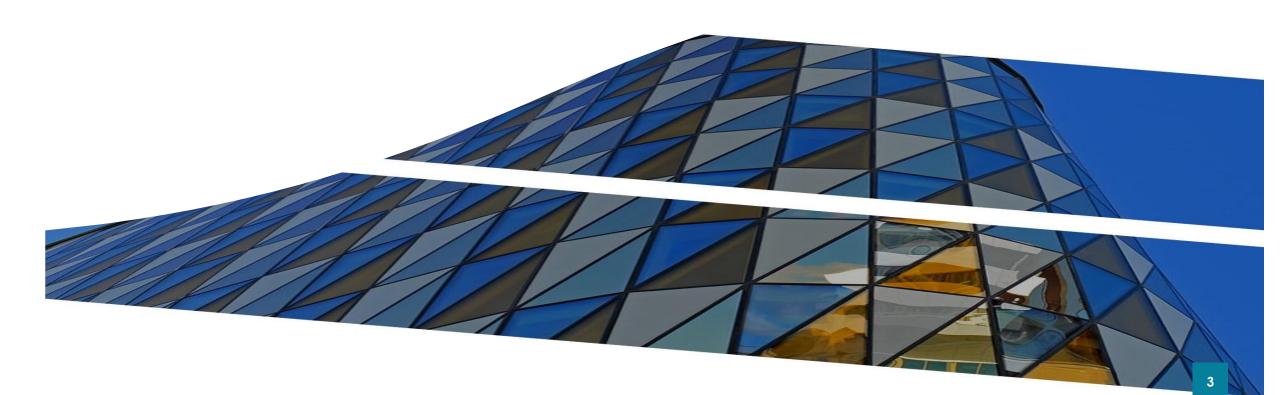

## About me

#### **Trayan Iliev**

- CEO of IPT Intellectual Products & Technologies
   <a href="http://www.iproduct.org">http://www.iproduct.org</a>
- Oracle® certified programmer 15+ Y
- end-to-end reactive fullstack apps with Java, ES6+,
   TypeScript, Angular, React and Vue.js
- 12+ years IT trainer: Spring, Java EE, Node.js, Express,
   GraphQL, SOA, REST, DDD & Reactive Microservices
- Voxxed Days, jPrime, Java2Days, jProfessionals, BGOUG, BGJUG, DEV.BG speaker
- Organizer RoboLearn hackathons and IoT enthusiast

# Classes

#### Classes and Constructors

Classes in Kotlin are declared using the keyword class:

```
class Person { /*...*/}
class Empty
```

• A class in Kotlin can have a primary constructor and one or more secondary constructors. The primary constructor is a part of the class header, and it goes after the class name and optional type parameters:

```
class Person constructor(firstName: String) { /*...*/}
```

• If the primary constructor does not have any annotations or visibility modifiers, the constructor keyword can be omitted:

```
class Person(firstName: String) { /*...*/}
```

#### Order of Initialization

 The primary constructor cannot contain any code. Initialization code can be placed in initializer blocks prefixed with the init keyword:

```
class InitOrderDemo(name: String) {
  val firstProperty = "First property: $name".also(::println) // 1
  init {
     println("First initializer block that prints ${name}") //2
  val secondProperty = "Second property: ${name.length}".also(::println) // 3
  init {
     println("Second initializer block that prints ${name.length}") // 4
```

## **Initializing Class Properties**

• Primary constructor parameters can be used in the initializer blocks. They can also be used in property initializers declared in the class body:

```
class Customer(name: String) {
   val customerKey = name.uppercase()
}
```

• Kotlin has a concise syntax for declaring properties and initializing them from the primary constructor (including default values):

```
class Person(val firstName: String, val lastName: String, var age: Int)
```

class Person(val firstName: String, val lastName: String, var isEmployed: Boolean = true)

### **Constructor with Modifiers / Annotations**

Trailing comas can be added if necessary:

```
class Person6(
   val firstName: String,
   val lastName: String,
   var age: Int, // trailing comma
) { /*...*/}
```

• If the constructor has annotations or visibility modifiers, the **constructor** keyword is required and the modifiers go before it:

class Customer2 public @Inject constructor(name: String) { /\*...\*/}

## **Secondary Constructors**

 A class can also declare one or more secondary constructors, which are prefixed with constructor:

```
class Person(val pets: MutableList<Pet> = mutableListOf())

class Pet {
   constructor(owner: Person) {
     owner.pets.add(this) // adds this pet to the list of its owner's pets
   }
}
```

## **Secondary Constructors - II**

```
class Person(val name: String, val pets: MutableList<Pet> = mutableListOf()) {
  override fun toString() = "$name's pets: $pets"
class Pet(val name: String) {
  constructor(name: String, owner: Person) : this(name) {
     owner.pets.add(this) // adds this pet to the list of its owner's pets
  override fun toString() = "Pet($name)"
fun main() {
  val ivan = Person("Ivan Petrov")
  val Johny = Pet("Johny", ivan)
  val Silvester = Pet("Silvester", ivan)
  val Caty = Pet("Caty", ivan)
  println(ivan) //Ivan Petrov's pets: [Pet(Johny), Pet(Silvester), Pet(Caty)]
```

## **Constructor Delegation**

- Code in initializer blocks effectively becomes part of the primary constructor. Delegation to the primary constructor happens as the first statement of a secondary constructor, so the code in all initializer blocks and property initializers is executed before the body of the secondary constructor.
- Even if the class has no primary constructor, the delegation still happens:

```
class Constructors {
    init {
        println("Init block")
    }
    constructor(i: Int) {
        println("Constructor $i")
    }
}
```

#### Private constructors and constructors with default values

• If you don't want your class to have a public constructor, declare an empty primary constructor with non-default visibility:

class DontCreateMe private constructor () { /\*...\*/}

 On the JVM, if all of the primary constructor parameters have default values, the compiler will generate an additional parameterless constructor which will use the default values. This makes it easier to use Kotlin with libraries such as Jackson or JPA that create class instances through parameterless constructors.

class Customer(val customerName: String = "")

## **Creating Class Instances**

```
data class Product(val name: String, val price: Double, var id: Int)
data class Invoice(
  val number:Int,
  val customer: Customer,
  val items: MutableList<Product> = mutableListOf()
val customer = Customer("Joe Smith")
val invoice = Invoice(1, customer)
println(invoice) // Invoice(number=1, customer=Customer: JOE SMITH, items=[])
```

Kotlin does not have a new keyword.

#### **Class Members**

- Constructors and initializer blocks
- Functions
- Properties
- Nested and inner classes
- Object declarations

#### Inheritance

 All classes in Kotlin have a common superclass, Any, which is the default superclass for a class with no supertypes declared:

class Example // Implicitly inherits from Any

- Any class has three methods: equals(), hashCode(), and toString(). Thus, these methods are defined for all Kotlin classes.
- By default, Kotlin classes are final they can't be inherited. To make a class inheritable, mark it with the open keyword:

open class Base(p: Int)

class Derived(p: Int) : Base(p)

#### Inheritance – base class initialization

• If the derived class has no primary constructor, then each secondary constructor has to initialize the base type using the **super** keyword or it has to delegate to another constructor which does. Different secondary constructors can call different constructors of the base type:

```
class Context
class AttributeSet
open class View(val ctx: Context) {
  private var attributes: AttributeSet = AttributeSet()
  constructor(ctx: Context, attrs: AttributeSet): this(ctx) {
     this attributes = attrs
class MyView : View {
  constructor(ctx: Context) : super(ctx)
  constructor(ctx: Context, attrs: AttributeSet) : super(ctx, attrs)
```

## **Overriding Methods**

```
open class Shape {
  open fun draw() { /*...*/}
  fun fill() { /*... */}
class Circle() : Shape() {
  override fun draw() { /*...*/}
open class Rectangle() : Shape() {
  final override fun draw() { /*...*/}
```

## **Overriding Properties**

```
open class Shape2 {
  open val vertexCount: Int = 0
class Rectangle2 : Shape2() {
  override val vertexCount = 4
interface Shape3 {
  val vertexCount: Int
class Rectangle3(override val vertexCount: Int = 4) : Shape3 // Always has 4 vertices
class Polygon3 : Shape3 {
  override var vertexCount: Int = 0 // Can be set to any number later
```

#### Derived class initialization order

```
open class Base(val name: String) {
  init { println("Initializing a base class") }
  open val size: Int =
     name.length.also { println("Initializing size in the base class: $it") }
class Derived(
  name: String,
  val lastName: String,
): Base(name.replaceFirstChar { it.uppercase() }.also { println("Argument for the base class: $it") }) {
  init { println("Initializing a derived class") }
  override val size: Int =
     (super.size + lastName.length).also { println("Initializing size in the derived class: $it") }
                                                  Argument for the base class: Ivan
                                                  Initializing a base class
fun main() {
                                                  Initializing size in the base class: 4
  val d = Derived("ivan", "Petrov")
                                                  Initializing a derived class
                                                  Initializing size in the derived class: 10
```

#### Derived class initialization order

- When the base class constructor is executed, the properties declared or overridden in the
  derived class have not yet been initialized. Using any of those properties in the base class
  initialization logic (either directly or indirectly through another overridden open member
  implementation) may lead to incorrect behavior or a runtime failure.
- When designing a base class, you should avoid using open members in the constructors, property initializers, or init blocks.

## Calling the superclass implementation

 Code in a derived class can call its superclass functions and property accessor implementations using the super keyword:

```
open class Rectangle4 {
  open fun draw() { println("Drawing a rectangle") }
  val borderColor: String get() = "black"
class FilledRectangle : Rectangle4() {
  override fun draw() {
     super.draw()
     println("Filling the rectangle")
  val fillColor: String get() = super.borderColor
```

## Calling the superclass implementation in inner class

```
class FilledRectangle2: Rectangle4() {
  override fun draw() {
     val filler = Filler()
     filler.drawAndFill()
  inner class Filler {
     fun fill() { println("Filling") }
     fun drawAndFill() {
       super@FilledRectangle2.draw() // Calls Rectangle's implementation of draw()
       fill()
       // Uses Rectangle's implementation of borderColor's get()
       println("Drawn a filled rectangle with color ${super@FilledRectangle2.borderColor}")
```

## **Overriding Rules**

- If a class inherits multiple implementations of the same member from its immediate superclasses, it must override this member and provide its own implementation (perhaps, using one of the inherited ones).
- To denote the supertype from which the inherited implementation is taken, use super qualified by the supertype name in angle brackets, such as super<Base>:

```
open class Rectangle5 {     open fun draw() { /* ... */ }  }
interface Polygon {     fun draw() { /* ... */ } // interface members are 'open' by default }

class Square() : Rectangle5(), Polygon { // The compiler requires draw() to be overridden:
     override fun draw() {
        super<Rectangle5>.draw() // call to Rectangle.draw()
        super<Polygon>.draw() // call to Polygon.draw()
    }
}
```

#### **Abstract Classes**

• A class may be declared **abstract**, along with some or all of its members. An abstract member does not have an implementation in its class. You don't need to annotate abstract classes or functions with open.

```
abstract class Polygon6 {
   abstract fun draw()
}

class Rectangle6 : Polygon6() {
   override fun draw() {
      // draw the rectangle
   }
}
```

```
open class Polygon7{
  open fun draw() {
     // some default polygon drawing method
  }
}
abstract class WildShape : Polygon7() {
     // Classes that inherit WildShape need to provide their own
     // draw method instead of using the default on Polygon
     abstract override fun draw()
}
```

#### **Interfaces**

 Interfaces in Kotlin can contain declarations of abstract methods, as well as method implementations. What makes them different from abstract classes is that interfaces cannot store a state. They can have properties, but these need to be abstract or provide accessor implementations.

```
interface MyInterface {
  fun bar()
  fun foo() {
     // optional body
class Child : MyInterface {
  override fun bar() {
     // body
```

```
interface MyInterface2 {
  val prop: Int // abstract
  val propertyWithImplementation: String
     get() = "foo"
  fun foo() {
     print(prop)
class Child2 : MyInterface2 {
  override val prop: Int = 29
```

## **Companion Objects**

- If you need to write a function that can be called without having a class instance but that needs access to the internals of a class (such as a factory method), you can write it as a member of an object declaration inside that class.
- Even more specifically, if you declare a companion object inside your class, you can access its members using only the class name as a qualifier.

```
class MyClass {
    companion object Factory {
        fun create(): MyClass = MyClass()
    }
}
val instance = MyClass.create()
```

```
class MyClass2 {
   companion object { }
}
val x = MyClass2.Companion
```

## **Examples**

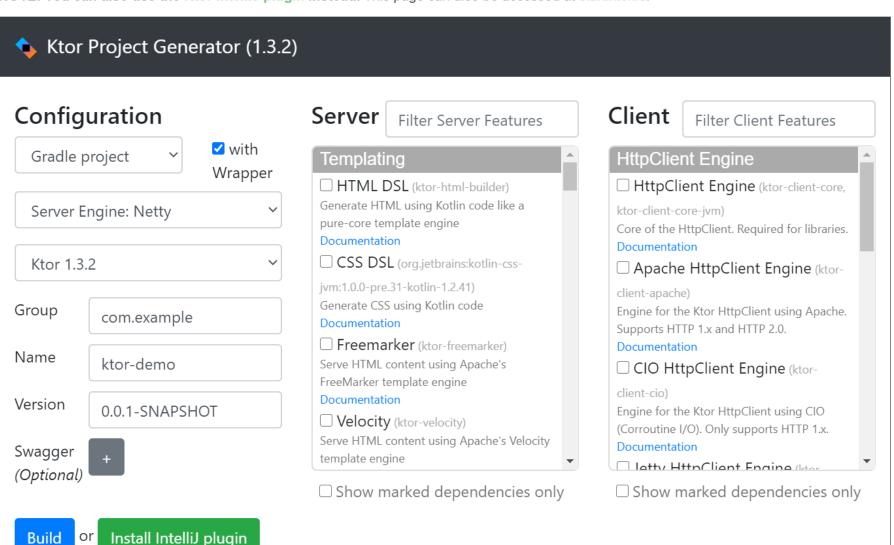

```
data class Product(val name: String, val price: Double)
class Order(val number: Int, val products: List<Product>, val date: LocalDateTime = LocalDateTime.now() ){
  fun calculateTotal(): Double {
     return products
       map { it.price }
       .reduce { acc, prod -> acc + prod }
// And if you check a type is right, the compiler will auto-cast it for you
fun calculateTotal(obj: Any): Double? {
  if (obj is Order) return obj.calculateTotal()
  return 0.0
fun main() {
  val products = listOf(Product("Keyboard", 27.5), Product("Mouse", 17.1))
  val order = Order(1, products)
  println(calculateTotal((order))); // => 44.6
```

## Simple Web Service with Ktor

```
fun main() {
  val server = embeddedServer(Netty, 8080) {
     routing {
       get("/hello") {
          call.respondText("<h2>Hello from Ktor and Kotlin!</h2>", ContentType.Text.Html)
  server.start(true)
... And that's all:)
```

```
data class Product(val name: String, val price: Double, var id: Int)
object Repo: ConcurrentHashMap<Int, Product>() {
  private idCounter = AtomicInteger()
  fun addProduct(product: Product) {
     product.id = idCounter.incrementAndGet()
    put(product.id, product)
fun main() {
  embeddedServer(Netty, 8080, watchPaths = listOf("build/classes"), module= Application::mymodule).start(true)
fun Application.mymodule() {
  install(DefaultHeaders)
  install(CORS) { maxAgeInSeconds = Duration.ofDays(1).toSeconds() }
  install(Compression)
  install(CallLogging)
  install(ContentNegotiation) {
    gson {
       setDateFormat(DateFormat.LONG)
       setPrettyPrinting()
```

```
routing {
    get("/products") {
       call.respond(Repo.values)
    get("/products/{id}") {
       try ·
         val item = Repo.get(call.parameters["id"]?.toInt())
         if (item == null) {
            call.respond(
               HttpStatusCode.NotFound,
               """{"error":"Product not found with id = ${call.parameters["id"]}"}"""
         } else {
            call.respond(item)
       } catch(ex :NumberFormatException) {
         call.respond(HttpStatusCode.BadRequest,
            """{"error":"Invalid product id: ${call.parameters["id"]}"}"")
```

```
post("/products") {
       errorAware {
          val product: Product = call.receive<Product>(Product::class)
          println("Received Post Request: $product")
          Repo.addProduct(product)
          call.respond(HttpStatusCode.Created, product)
private suspend fun <R> PipelineContext<*, ApplicationCall>.errorAware(block: suspend () -> R): R? {
  return try {
     block()
  } catch (e: Exception) {
     call.respondText(
       """{"error":"$e"}""",
       ContentType.parse("application/json"),
       HttpStatusCode.InternalServerError
     null
```

## **Ktor Applications**

- Ktor Server Application is a custom program listening to one or more ports using a configured server engine, composed by modules with the application logic, that install features, like routing, sessions, compression, etc. to handle HTTP/S 1.x/2.x and WebSocket requests.
- ApplicationCall the context for handling routes, or directly intercepting the pipeline – provides access to two main properties ApplicationRequest and ApplicationResponse, as well as request parameters, attributes, authentication, session, typesafe locations, and the application itself. Example:

```
intercept(ApplicationCallPipeline.Call) {
   if (call.request.uri == "/")
      call.respondHtml {
      body {
         a(href = "/products") { + "Go to /products" }
} } }
```

## **Routing DSL Using Higher Order Functions**

- routing, get, and post are all higher-order functions (functions that take other functions as parameters or return functions).
- Kotlin has a convention that if the last parameter to a function is another function, we can place this outside of the brackets
- routing is a lambda with receiver == higher-order function taking as parameter an extension function => anything enclosed within routing has access to members of the type Routing.
- get and post are functions of the Routing type => also lambdas with receivers, with own members, such as call.
- This combination of **conventions** and **functions** allows to create elegant DSLs, such as Ktor's **routing DSL**.

#### **Features**

- A feature is a singleton (usually a companion object) that you can install and configure for a pipeline.
- Ktor includes some standard features, but you can add your own or other features from the community.
- You can install features in any pipeline, like the application itself, or specific routes.
- Features are injected into the request and response pipeline. Usually, an
  application would have a series of features such as DefaultHeaders which
  add headers to every outgoing response, Routing which allows us to
  define routes to handle requests, etc.

## **Installing Features**

#### Using install: **Using routing DSL:** fun Application.main() { fun Application.main() { install(DefaultHeaders) *install*(DefaultHeaders) install(CallLogging) install(CallLogging) install(Routing) { routing { get("/") { get("/") { call.respondText("Hello, World!") call.respondText("Hello, World!")
